Peer Review 1: *<title of the paper you are reviewing>*

Anonymous reviewer
Green IT 2026 (MICS2-63)
Master in Information and Computer Sciences, University of Luxembourg
Compiled October 19, 2026.

Every italic note in this document is guidance. Delete each one as you write its section, then set `\guidancefalse` *in the preamble: the PDF you submit carries no guidance.*

The sections below are the parts of the paper, in the paper's own order. Write about each one where it belongs: a defect goes in the section it affects.

Reviews are double-blind. Your name stays out of this document. Your submission on Moodle is what tells the instructor the review is yours. The instructor numbers the reviews when he forwards them, from the author's side, so this file being your first review says nothing about the number it arrives under.

The paper you receive comes without its AI Usage Journal, which the author wrote and the instructor marks separately, and with an archive holding the script you are asked to run in Section IV.

This review carries no score of any kind. Each author receives two reviews of their paper. Marks reach students in mid-February.

I. Introduction

What question does the paper set out to answer, and does the paper answer it? Take the claims the introduction makes and say whether the rest of the paper supports them.

II. Related Work

Check the references. Do they exist, and do they say what they are cited for? Then judge whether the section situates the author's own contribution, or only lists other people's.

III. Life Cycle Assessment

Judge each subsection of III on whether it does its job. Then recompute the baseline from what the paper gives you, and put your figure in Table I. Section III.B declares what makes the paper's numbers reproducible: for a web page, whether it arrives compressed and on what date that was read, so recompute the bytes on that basis; for an HPC job, the commit, the fixed input and the exclusive node it ran on. If you cannot recompute it, say precisely what is missing.

IV. Optimisation and Payback

Run the script from the archive distributed with the paper and report what happened. Keep a scientific finding apart from an environment problem.

Recompute the remaining figures of Table I. A before and an after are comparable when they are produced the same way: for a web page, the same server started with the same compression setting; for an HPC job, the same partition and node type with the same fixed input. Check that Section IV says which. Then judge whether the optimisation and the payback follow from what Section III found.

TABLE I
Recomputation of the author's key figures.

Quantity	Author	Reviewer	Comment
Baseline, live page or job			
Before optimisation, frozen copy or original job			
After optimisation			
Development cost			
Payback (page views or runs)			

V. Threats to Validity

Judge the threats the author lists, then name one they did not. If you looked and found none, say where you looked.

VI. Recommendation

One word: ACCEPT or REJECT. Those are the two options. Taking one of them is what this section is for.

Then two or three lines saying why this verdict follows from what you wrote above. Which side you take is yours.

VII. Actionable Recommendations

For each issue you raised above, what the author should do. Concrete enough to carry out before Fri 18 Dec.
